# Answering Queries from Statistics and Probabilistic Views 

Nilesh Dalvi and Dan Suciu, University of Washington.

## Background

- 'Query answering using Views' problem: find answers to a query $q$ over a database schema $R$ using a set of views $V=\left\{\mathrm{v}_{1}, \mathrm{v}_{2} \cdots\right\}$ over $R$.
- Example: $R$ (name,dept,phone)
$\mathrm{V}_{1}(\mathrm{n}, \mathrm{d}): R(\mathrm{n}, \mathrm{d}, \mathrm{p})$

$\mathrm{v}_{1}=$| NAME | DEPT |
| :---: | :---: |
| LARRY | SALES |
| JOHN | SALES |

| $\mathrm{v}_{2}(\mathrm{~d}, \mathrm{p}): R(\mathrm{n}, \mathrm{d}, \mathrm{p})$ |
| :---: |
| $\mathrm{v}_{2}=$DEPT PHONE <br> SALES $\times 1234$ <br> SALES $\times 5678$ <br> HR $\times 2222$ |

$$
q(\mathrm{p}): R(\mathrm{LARRY}, \mathrm{~d}, \mathrm{p})
$$

## Background: Certain Answers

Let $U$ be a finite universe of size n . Consider all possible data instances over $U$

| $\mathrm{D}_{1}$ | $\mathrm{D}_{2}$ | $\mathrm{D}_{3}$ | $\mathrm{D}_{4}$ | $\ldots \ldots$. | $\mathrm{D}_{\mathrm{m}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |

Data instances consistent with the views $V$

Certain Answers: tuples that occur as answers in all data instances consistent with $V$

## Example

$$
\begin{gathered}
\mathrm{v}_{1}(\mathrm{n}, \mathrm{~d}): \mathrm{R}(\mathrm{n}, \mathrm{~d}, \mathrm{p}) \\
\mathrm{v}_{1}=\begin{array}{|c|c|}
\hline \text { NAME } & \text { DEPT } \\
\hline \text { LARRY } & \text { SALES } \\
\hline \text { JOHN } & \text { SALES } \\
\hline
\end{array}
\end{gathered}
$$

| $\mathrm{v}_{2}(\mathrm{~d}, \mathrm{p}): \mathrm{R}(\mathrm{n}, \mathrm{d}, \mathrm{p})$ |
| :---: |
| $\mathrm{v}_{2}=$DEPT PHONE <br> SALES $\times 1234$ <br> SALES $\times 5678$ <br> HR $\times 2222$ |

$$
q(\mathrm{p}): \mathrm{R}(\mathrm{LARRY}, \mathrm{~d}, \mathrm{p})
$$

Data instances consistent with the views:

| $\mathrm{D}_{1}=$ |  |  |
| :--- | :--- | :--- |
| NAME | DEPT | PHONE |
| LARRY | SALES | $\times 1234$ |
| JOHN | SALES | $\times 5678$ |
| SUE | HR | $\times 2222$ |

$\mathrm{D}_{2}=$

| NAME | DEPT | PHONE |
| :--- | :--- | :--- |
| FRANK | SALES | $\times 5678$ |
| LARRY | SALES | X1111 |
| JOHN | SALES | X1234 |
| SUE | HR | $\times 2222$ |

## Example (contd.)

$$
V_{1}=\begin{array}{|c|c|}
\hline \text { NAME } & \text { DEPT } \\
\hline \text { LARRY } & \text { SALES } \\
\hline \text { JOHN } & \text { SALES } \\
\hline
\end{array}
$$

$V_{2}=$| DEPT | PHONE |
| :---: | :---: |
| SALES | $\times 1234$ |
| SALES | $\times 5678$ |
| HR | $\times 2222$ |

- No certain answers, but some answers are more likely that others.
- Domain is huge, cannot just guess Larry's number.
- A data instance is much smaller. If we know average employes per dept $=5$, then $\times 1234$ and $\times 5678$ have 0.2 probability of being answer.

## Going beyond certain answers

- Certain answers approach assumes complete ignorance about the knowledge of how likely is each possible database
- Often we have additional knowledge about the data in form of various statistics

Can we use such information to find answers to queries that are statistically meaningful?

## Why Do We Care?

- Data Privacy: publishers can analyze the amount of information disclosed by public views about private information in the database
- Ranked Search: a ranked list of probable answers can be returned for queries with no certain answers.

## Using Common Knowledge

- Suppose we have a priori distribution Pr over all possible databases:

$$
\operatorname{Pr}:\left\{D_{1}, \ldots, D_{m}\right\} \rightarrow[0,1]
$$

- We can compute the probability of a tuple $t$ being an answer to $q$ using $\operatorname{Pr}[(t \in q) \mid V]$

Query Answering using views = Computing conditional probabilities on a distribution

## Part I

## 2uery answering using vieres under some specific distributions

## Binomial Distribution

$U$ : a domain of size n
We start from a simple case

- R (name,dept,phone) a relation of arity 3
- Expected size of R is c

Binomial: Choose each of the $\mathrm{n}^{3}$ possible tuples independently with probability $p$.

Expected size of $R$ is $c \Rightarrow p=c / n^{3}$
Let $\mu_{\mathrm{n}}$ denote the resulting distribution. For any instance D,

$$
\mu_{\mathrm{n}}[\mathrm{D}]=\mathrm{p}^{\mathrm{k}}(1-\mathrm{p})^{\mathrm{n}^{3}-\mathrm{k}}, \text { where } \mathrm{k}=|\mathrm{D}|
$$

## Binomial: Example I

R(name,dept,phone)
v : R(LARRY, -, -)
$\mathrm{q}: \mathrm{R}(-,-, \times 1234)$
$|\mathrm{R}|=\mathrm{c}$, domain size $=\mathrm{n}$
$\mu_{n}[q \mid v] \approx(c+1) / n=$ negligible if $n$ is large
$\lim _{\mathrm{n}} \rightarrow \infty \mu_{\mathrm{n}}[\mathrm{q} \mid v]=0$
v gives negligible information about q when domain is large

## Binomial: Example II

R (name, dept, phone) $\quad|\mathrm{R}|=\mathrm{c}$, domain size $=\mathrm{n}$
$\mathrm{v}: \mathrm{R}($ LARRY,,--$), \mathrm{R}(-,-, \times 1234)$
$\mathrm{q}: \mathrm{R}$ (LARRY,,$- \times 1234$ )
$\lim _{n \rightarrow \infty} \mu_{n}[q \mid v]=1 /(1+c)$
v gives non-negligible information about q , even for large domains

## Binomial: Example III

R (name, dept, phone) $\quad|\mathrm{R}|=\mathrm{c}$, domain size $=\mathrm{n}$ $\mathrm{v}: \mathrm{R}($ LARRY, SALES,,-$), \mathrm{R}(-$, Sales, $\times 1234)$ $\mathrm{q}: \mathrm{R}$ (LARRY, SALES, $\times 1234$ )
$\lim _{\mathrm{n}} \rightarrow \infty \mu_{\mathrm{n}}[\mathrm{q} \mid v]=1$
Binomial distribution cannot express more interesting statistics.

## A Variation on Binomial

- Suppose we have following statistics on R(name,dept,phone):
- $\quad$ Expected number of distinct R.dept $=\mathrm{c}_{1}$
- Expected number of distinct tuples for each R.dept $=c_{2}$
- Consider the following distribution $\mu_{\mathrm{n}}$
- For each $\mathrm{x}_{\mathrm{d}} \in \mathrm{U}$, choose it as a R.dept value with probability $\mathrm{c}_{1} / \mathrm{n}$
- For each $\mathrm{x}_{\mathrm{d}}$ chosen above, for each $\left(\mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{p}}\right) \in \mathrm{U}^{2}$, include the tuple ( $\mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{d}}, \mathrm{x}_{\mathrm{p}}$ ) in R with probability $\mathrm{c}_{2} / \mathrm{n}^{2}$

## Examples

R (name, dept, phone) $|\mathrm{dept}|=\mathrm{c}_{1}$, $\mid$ dept $\Rightarrow$ name, phone $\left|=\mathrm{c}_{2},|\mathrm{R}|=\mathrm{c}_{1} \mathrm{c}_{2}\right.$
Example i:

$$
\begin{aligned}
& \mathrm{v}: \mathrm{R}(\text { LARRY },-,-), \mathrm{R}(-,-, \times 1234) \\
& \mathrm{q}: \mathrm{R}(\text { LARRY, }-, \times 1234) \\
& \mu[\mathrm{q} \mid \mathrm{v}]=1 /\left(\mathrm{c}_{1} \mathrm{c}_{2}+1\right)
\end{aligned}
$$

Example 2:

$$
\begin{aligned}
& \mathrm{v}: \mathrm{R}(\text { LARRY, SALES, }-), \mathrm{R}(-, \text { SALES, } \times 1234) \\
& \mathrm{q}: \mathrm{R}(\text { LARRY, SALES, } \times 1234) \\
& \mu[\mathrm{q} \mid \mathrm{v}]=1 /\left(\mathrm{c}_{2}+1\right)
\end{aligned}
$$

## Part II : Representing Knowledge as a Probability Distribution

## Knowledge about data

- A set of statistics $\Gamma$ on the database
- cardinality statistics : $\operatorname{card}_{\mathrm{R}}[\mathrm{A}]=\mathrm{c}$
- fanout statistics: fanout ${ }_{R}[A \Rightarrow B]=c$
- A set of integrity constraints $\Sigma$
- functional dependencies: R.A $\rightarrow$ R.B
- inclusion dependencies: R.A $\subseteq$ R.B

## Representing Knowledge

Statistics and constraints are statements on the probability distribution P
$-\operatorname{card}_{\mathrm{R}}[\mathrm{A}]=\mathrm{c}$ implies the following

$$
\Sigma_{\mathrm{i}} \mathrm{P}\left[\mathrm{D}_{\mathrm{i}}\right] \operatorname{card}\left(\Pi_{\mathrm{A}}\left(\mathrm{R}^{\mathrm{D}_{\mathrm{i}}}\right)\right)=\mathrm{c}
$$

- fanout ${ }^{[ }[A \Rightarrow B]$ implies a similar condition
- A constraint $\Sigma$ implies that $\mathrm{P}\left[\mathrm{D}_{\mathrm{i}}\right]=0$ on data instances $D_{i}$ that violate $\Sigma$
Problem: P is not uniquely defined by these statements!

## The Maximum Entropy Principle

- Among all the probability distributions that satisfy $\Sigma$ and $\Gamma$, choose the one with maximum entropy.
- Widely used to convert prior information into prior probability distribution
- Gives a distribuion that commits the least to any specific instance while satisfying all the equations.

## Examples of Entropy Maximization

- R (name, dept,phone) a relation of arity 3
- Example I:

$$
\Gamma=\operatorname{empty}, \Sigma=\{\operatorname{card}[R]=c\}
$$

Entropy maximizing distribution = Binomial

- Example 2:

$$
\begin{aligned}
& \Gamma=\text { empty, } \Sigma=\left\{\operatorname{card}_{\mathrm{R}}[\mathrm{dept}]=\mathrm{c}_{1}\right. \text {, } \\
& \text { fanout } \left.{ }_{R}[\text { dept } \Rightarrow \text { name,phone }]=c_{2}\right\}
\end{aligned}
$$

Entropy maximizing distribution $=$ variation on Binomial distribution we studies earlier.

## Query answering problem

Given a set of statistics $\Sigma$ and constraints $\Gamma$, let $\mu_{\Sigma, \Gamma, \mathrm{n}}$ denote the maximum entropy distribution assuming a domain of size $n$.

Problem: Given statistics $\Sigma$, constraints $\Gamma$, and boolean conjunctive queries $q$ and $v$, compute the asymptotic limit of $\mu_{\Sigma, \Gamma, n}[q \mid v]$ as $n \rightarrow \infty$

## Main Result

- For Boolean conjunctive queries $q$ and $v$, the quantity $\mu_{\Sigma, \Gamma, \mathrm{n}}[\mathrm{q} \mid \mathrm{v}]$ always has an asymptotic limit and we show how to compute it.

## Glimpse into Main Result

- For any conjunctive query Q, we show that $\mu_{\Sigma, \Gamma, n}[Q]$ is a polynomial of the form

$$
c_{1}(1 / n)^{d}+c_{2}(1 / n)^{d+1}+\ldots
$$

- $\mu_{\Sigma, \Gamma, \mathrm{n}}[q \mid v]=\mu_{\Sigma, \Gamma, \mathrm{n}}[q v] / \mu_{\Sigma, \Gamma, \mathrm{n}}[\mathrm{v}]=$ ratio of two polynomials.
- Only the leading coefficient and exponent matter, and we show how to compute them.

## Conclusions

- We show how to use common knowledge about data to find answers to queries that are statistically meaningful
- Provides a formal framework for studying database privacy breaches using statistical attacks.
- We use the principle of entropy maximization to represent statistics as a prior probability distribution.
- The techniques are also applicable when the contents of views are themselves uncertain.

## Questions?
